TITLE

## POLYMERIZATION OF OLEFINS

This application claims the benefit of U.S.

5 Provisional Application No. 60/035,190, filed  
January 14, 1997.

FIELD OF THE INVENTION

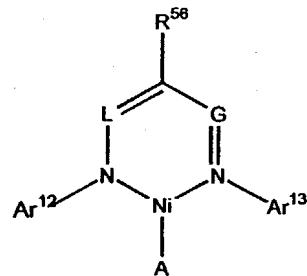

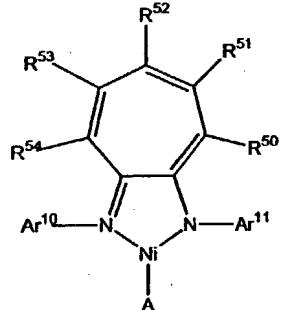

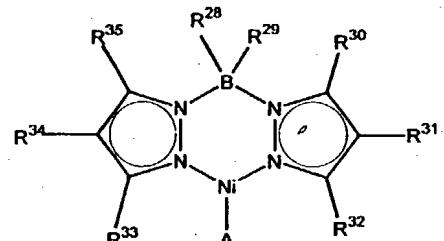

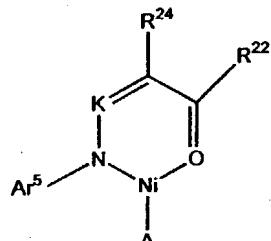

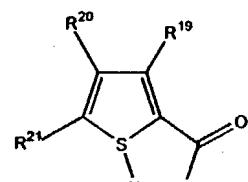

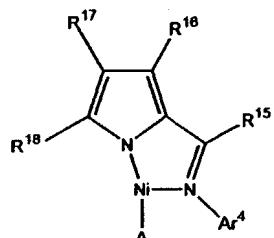

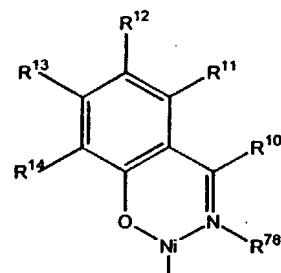

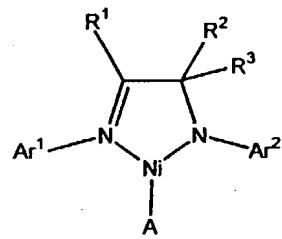

Olefins are polymerized by a catalyst system that  
10 includes a nickel[II] complexes of selected monoanionic  
bidentate ligands. Some of these complexes are also  
novel.

TECHNICAL BACKGROUND

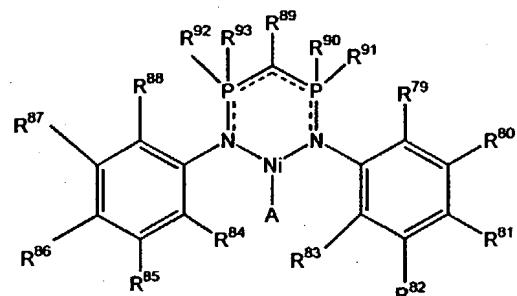

Polymers of ethylene and other olefins are  
15 important items of commerce, and these polymers are  
used in a myriad of ways, from low molecular weight  
polyolefins being used as a lubricant and in waxes, to  
higher molecular weight grades being used for fiber,  
films, molding resins, elastomers, etc. In most cases,  
20 olefins are polymerized using a catalyst, often a  
transition metal compound or complex. These catalysts  
vary in cost per unit weight of polymer produced, the  
structure of the polymer produced, the possible need to  
remove the catalyst from the polyolefin, the toxicity  
25 of the catalyst, etc. Due to the commercial importance  
of polymerizing olefins, new polymerization catalysts  
are constantly being sought.

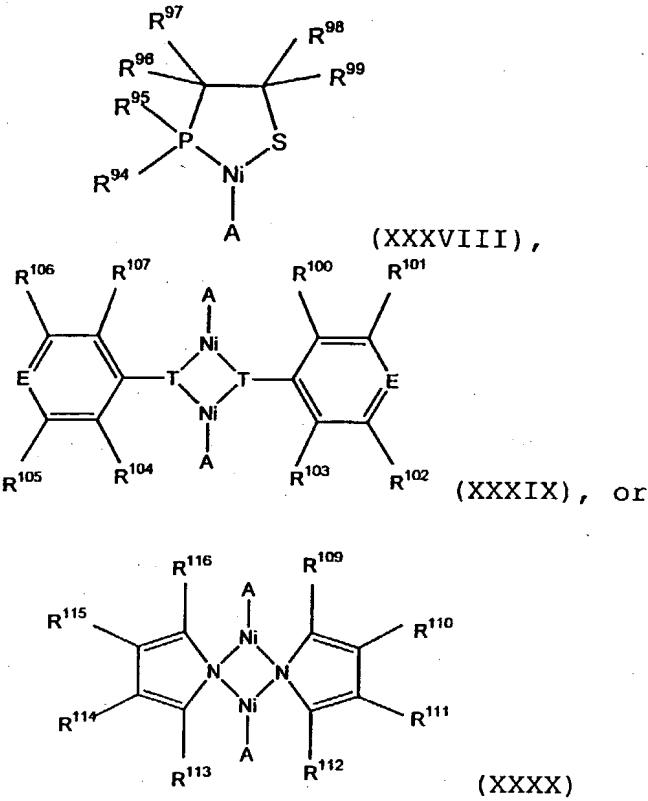

SUMMARY OF THE INVENTION

This invention concerns a process for the  
30 polymerization of an olefin selected from one or more  
of  $R^{67}CH=CH_2$ , cyclopentene, a styrene, a norbornene or  
 $H_2C=CH(CH_2)_sCO_2R^{77}$ , comprising, contacting, at a  
temperature of about  $-100^{\circ}C$  to about  $+200^{\circ}C$ ,  $R^{67}CH=CH_2$ ,  
cyclopentene, a styrene, a norbornene, or  
35  $H_2C=CH(CH_2)_sCO_2R^{77}$ , optionally a Lewis acid, and a  
compound of the formula:

#### DETAILS OF THE INVENTION

Herein, certain terms are used. Some of them are:

• A "hydrocarbyl group" is a univalent group containing only carbon and hydrogen. If not otherwise stated, it is preferred that hydrocarbyl groups herein 20 preferably contain 1 to about 30 carbon atoms.

• By "substituted hydrocarbyl" herein is meant a hydrocarbyl group which contains one or more substituent groups which are inert under the process conditions to which the compound containing these 25 groups is subjected. The substituent groups also do not substantially interfere with the process. If not otherwise stated, it is preferred that substituted hydrocarbyl groups herein contain preferably 1 to about 30 carbon atoms. Included in the meaning of 30 "substituted" are heteroaromatic rings.

• By "(inert) functional group" herein is meant a group other than hydrocarbyl or substituted hydrocarbyl which is inert under the process conditions to which the compound containing the group is 35 subjected. The functional groups also do not substantially interfere with any process described herein that the compound in which they are present may take part in. Examples of functional groups include

halo (fluoro, chloro, bromo and iodo), ether such as -<sup>25</sup>OR<sup>25</sup>, -CO<sub>2</sub>R<sup>25</sup>, -NO<sub>2</sub>, and -NR<sup>25</sup><sub>2</sub>, wherein R<sup>25</sup> is hydrocarbyl or substituted hydrocarbyl. In cases in which the functional group may be near a nickel atom 5 the functional group should not coordinate to the metal atom more strongly than the groups in compounds which are shown as coordinating to the metal atom, that is they should not displace the desired coordinating group.

10 • By a "polymerization process" herein (and the polymers made therein) is meant a process which produces a polymer with a degree of polymerization (DP) of about 5 or more, preferably about 10 or more, more preferably about 40 or more [except where otherwise 15 noted, as in P in compound (XVII)]. By "DP" is meant the average number of repeat (monomer) units in the polymer.

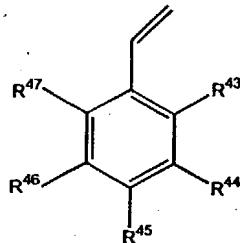

20 • By "aryl" herein is meant a monovalent radical whose free valence is to a carbon atom of an aromatic ring. Unless otherwise noted herein, preferred aryl groups contain carbocyclic rings, but heterocyclic rings are also included within the 25 definition of "aryl". The aryl radical may contain one ring or may contain 2 or more fused rings, such as 9-anthracenyl or 1-naphthyl. Unless otherwise stated aryl groups preferably contain 5 to 30 carbon atoms.

30 • By "substituted aryl" herein is meant an aryl radical substituted with one or more groups that do not interfere with the synthesis of the compound or the resulting polymerization. Suitable substituents include alkyl, aryl such as phenyl, halo, alkoxy, ester, dialkylamino and nitro. Unless otherwise stated, substituted aryl groups contain 5 to about 30 carbon atoms.

35 • By a "monoanionic ligand" is meant a ligand with one negative charge.

• By a "neutral ligand" is meant a ligand that is not charged.

- "Alkyl group" and "substituted alkyl group" have their usual meaning (see above for substituted under substituted hydrocarbyl). Unless otherwise stated, alkyl groups and substituted alkyl groups 5 preferably have 1 to about 30 carbon atoms.
- By a styrene herein is meant a compound of the formula

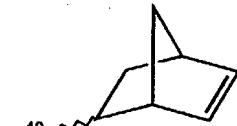

(XXXIV)

10 wherein  $R^{43}$ ,  $R^{44}$ ,  $R^{45}$ ,  $R^{46}$  and  $R^{47}$  are each independently hydrogen, hydrocarbyl, substituted hydrocarbyl or a functional group, all of which are inert in the polymerization process. It is preferred that all of  $R^{43}$ ,  $R^{44}$ ,  $R^{45}$ ,  $R^{46}$  and  $R^{47}$  are hydrogen.

15 Styrene (itself) is a preferred styrene.

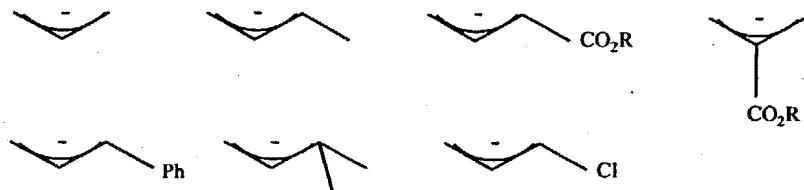

- By a norbornene is meant ethyldene norbornene, dicyclopentadiene, or a compound of the formula

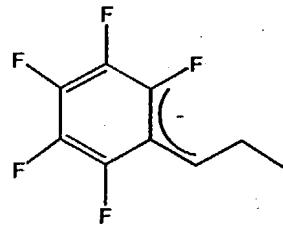

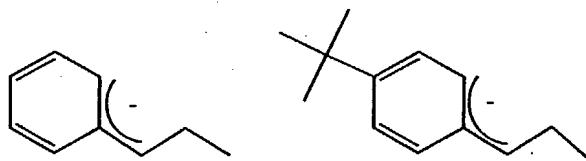

(XXXV);

20 wherein  $R^{40}$  is hydrogen or hydrocarbyl containing 1 to 20 carbon atoms. It is preferred that  $R^{40}$  is hydrogen or alkyl, more preferably hydrogen or n-alkyl, and especially preferably hydrogen. The norbornene may be 25 substituted by one or more hydrocarbyl, substituted hydrocarbyl or functional groups in the  $R^{40}$  or other positions, with the exception of the vinylic hydrogens, which remain. Norbornene (itself), dimethyl endo-norbornene-2,3-dicarboxylate, t-butyl 5-norbornene-2-carboxylate are preferred norbornenes and norbornene 30 (itself) is especially preferred.

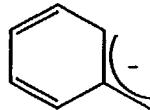

- By a  $\pi$ -allyl group is meant a monoanionic ligand with 3 adjacent  $sp^2$  carbon atoms bound to a metal center in an  $\eta^3$  fashion. The three  $sp^2$  carbon atoms may be substituted with other hydrocarbyl groups or functional groups. Typical  $\pi$ -allyl groups include

wherein R is hydrocarbyl. By a  $\pi$ -benzyl group is meant 10  $\pi$ -allyl ligand in which two of the  $sp^2$  carbon atoms are part of an aromatic ring. Typical  $\pi$ -benzyl groups include

and

15

$\pi$ -Benzyl compounds usually initiate polymerization of the olefins fairly readily even at room temperature, but  $\pi$ -allyl compounds may not necessarily do so. Initiation of  $\pi$ -allyl compounds can be improved by 20 using one or more of the following methods:

- Using a higher temperature such as about 80°C.

- Decreasing the bulk of the monoanionic ligand, such as aryl being 2,6-dimethylphenyl instead of 2,6-diisopropylphenyl.
- Making the  $\pi$ -allyl ligand more bulky, such as using

rather than the simple  $\pi$ -allyl group itself.

- Having a Lewis acid or a material that acts as a Lewis acid present while using a  $\pi$ -allyl or  $\pi$ -benzyl group, especially a functional  $\pi$ -allyl or  $\pi$ -benzyl group. Relatively weak Lewis acids such as triphenylborane, tris(pentafluorophenyl)borane, tris(3,5-trifluoromethylphenyl)borane, and poly(methylaluminoxane) are preferred. Suitable functional groups include chloro and ester.

Lewis acids may also be optionally present when compounds containing  $L^1$  and/or  $L^2$  are present in the polymerization, even when  $L^2$  is not a  $\pi$ -allyl or  $\pi$ -benzyl group. It is believed that the Lewis acid, if present, may help to remove  $L^1$  (if present) from the nickel atom, thereby facilitating the coordination of the olefin to the Ni atom. If a compound containing  $L^1$  and/or  $L^2$  does not act as a polymerization catalyst, it is suggested that a Lewis acid, such as those mentioned above be added to the process to determine if polymerization will then take place. Such testing requires minimal experimentation, and is illustrated in the Examples. Not surprisingly, with any particular set of polymerization process ingredients, some Lewis acids may be more effective than others.

In preferred olefins herein,  $R^{67}$  is hydrogen or n-alkyl containing 1 to 20 carbon atoms (an  $\alpha$ -olefin), more preferably n-alkyl containing 1 to 8 carbon atoms, or more preferably hydrogen (e.g., ethylene) or methyl (e.g., propylene), and especially preferably hydrogen. A combination of ethylene and  $H_2C=CHR^{67}$  wherein  $R^{67}$  n-alkyl containing 1 to 8 carbon atoms is also

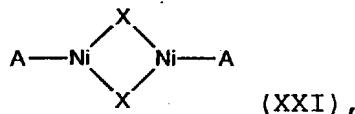

preferred, and a combination of ethylene and propylene is more preferred. It is also preferred that s is 2 or more, and/or R<sup>77</sup> is alkyl, especially preferably methyl or ethyl. When H<sub>2</sub>C=CH(CH<sub>2</sub>)<sub>s</sub>CO<sub>2</sub>R<sup>77</sup> is present as one of 5 the olefins, it is preferred that R<sup>67</sup> is hydrogen.

While not all homopolymers and copolymers of the olefinic monomers useful herein can be made using the polymerization processes described herein, most homopolymers and many copolymers can be made. The 10 following homopolymers can be readily made in these polymerization processes: polyethylene, polystyrene, a polynorbornene, poly- $\alpha$ -olefins (often lower molecular weight polymers obtained), polycyclopentene (often lower molecular weight polymers obtained). Attempted 15 homopolymerization of functionalized norbornenes often does not proceed, nor do homopolymerizations of compounds of the formula H<sub>2</sub>C=CH(CH<sub>2</sub>)<sub>s</sub>CO<sub>2</sub>R<sup>77</sup>. Many copolymers can be made, including ethylene/ $\alpha$ -olefins, styrene/norbornene copolymers, copolymers of 2 or more 20 norbornenes including functionalized norbornenes, copolymers of ethylene and cyclopentene, copolymers of ethylene and a norbornene, and copolymers of ethylene and H<sub>2</sub>C=CH(CH<sub>2</sub>)<sub>s</sub>CO<sub>2</sub>R<sup>77</sup>.

Not every variation of every nickel complex listed 25 in the various polymerizations will make every one of the polymers listed immediately above. However, many of them will make most if not all of these types of polymers. While no hard and fast rules can be given, it is believed that for polymerizations which include 30 ethylene and/or  $\alpha$ -olefins, steric hindrance about the nickel atom caused by substituent groups is desirable for making polymers, especially higher molecular weight polymers, while for polymers containing one or more of a styrene and/or a norbornene such steric hindrance is 35 not as important.

The Ni[II] complexes that are useful herein for the polymerization of ethylene contain a bidentate monoanionic ligand (other than a combined L<sup>1</sup> and L<sup>2</sup>) in

which the coordinating atoms are 2 nitrogen atoms, a nitrogen atom and an oxygen atom, a phosphorous atom and a sulfur atom, or an oxygen atom and a sulfur atom. Compounds of formulas (I) through (VI), (XVIII), (XXVII), and (XXXVII)-(XXXX) can be made by reaction of 2 moles of the anionic form of the ligand with one mole of the appropriate nickel allyl or benzyl precursor (XXI),

wherein X is preferably chlorine or bromine and A is a  $\pi$ -allyl or  $\pi$ -benzyl group, to form the nickel compound (see Examples 17-40 and 469-498).

Compounds of formulas (VII) through (XII), (XIX), (XXVIII), and (XXXI)-(XXXXIV) can be synthesized by protonation of a suitable Ni[0] or Ni[II] precursor by the neutral ligand or by reaction of a suitable Ni[II] precursor with the anionic form of the ligand.

Examples of suitable Ni[0] and Ni[II] precursors include  $\text{Ni}(1,4\text{-cyclooctadiene})_2$ ,

(N,N,N',N'-tetramethylethylenediamine)NiMe<sub>2</sub>, 2,2'-bipyridineNiMe<sub>2</sub>, (MePPh<sub>2</sub>)<sub>3</sub>NiMe<sub>2</sub>, [Ni(OMe)Me(PPh<sub>3</sub>)]<sub>2</sub>, [Ni(OMe)Me(PMe<sub>3</sub>)]<sub>2</sub>, NiBr<sub>2</sub>,

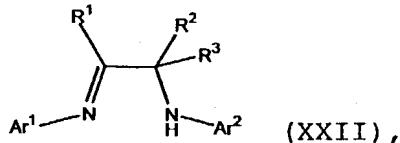

N,N,N',N'-tetramethylethylenediamine)Ni(acetylacetone)<sub>2</sub>, (1,2-dimethoxyethane)NiBr<sub>2</sub>,

N,N,N',N'-tetramethylethylenediamine)Ni(CH<sub>2</sub>=CHCO<sub>2</sub>CH<sub>3</sub>)<sub>2</sub>, (pyridine)<sub>2</sub>Ni(CH<sub>2</sub>=CHCO<sub>2</sub>CH<sub>3</sub>)<sub>2</sub>, and (acetylacetone)Ni(Et)(PPh<sub>3</sub>). The addition of phosphine or ligand "sponges" such as CuCl, BPh<sub>3</sub> or tris(pentafluorophenyl)borane may aid such reactions.

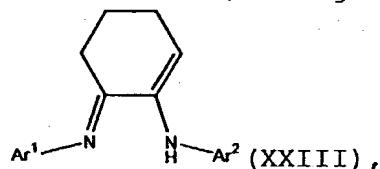

Some of the nickel compounds herein such as (XXXIX), (XXXX), (XXXXIII) and (XXXXIV) may exist as "dimers" or monomers, or in equilibrium between the two. The dimer contains two nickel atoms, each nickel atom being coordinated to L<sup>1</sup> and L<sup>2</sup>, wherein L<sup>1</sup> and L<sup>2</sup> combined may be a bidentate monoanionic ligand such as a  $\pi$ -allyl or  $\pi$ -benzyl group, and both Ni atoms "share" coordination to each of the other ligands present. As

described herein, depiction of the monomeric compound also includes the dimeric compound, and vice versa. Whether any particular nickel compound is (predominantly) a monomer or dimer, or both states are 5 detectable will depend on the ligands present. For instance it is believed that as the ligands become more bulky, especially about the nickel atom, the tendency is to form a monomeric compound.

Ligands for compounds (I) and (VII) of the formula

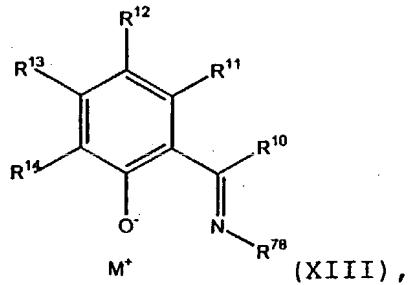

can be made by reaction of an alpha-diimine of the formula  $\text{Ar}^1\text{N}=\text{CR}^1-\text{CR}^2=\text{NAr}^2$  with one equivalent of a compound of the formula  $\text{R}^3\text{Li}$ , see for instance M. G. Gardner, et al., Inorg. Chem., vol. 34 p. 4206-15 4212 (1995). In another case, a ligand of the formula

can be made by the condensation of 1,2-cyclohexadione with the corresponding aromatic amine(s), see for instance R. van Asselt, et. al, Recl. Trav. Chim. Pays-Bas, vol. 113, p. 88-98 (1994). Note that in (XXIII) R¹, R² and R³ taken together form a ring, with R² and R³ both "part of" a double bond to the same carbon atom. These ligands can then be converted to their corresponding nickel complexes by the methods described above.

Compounds of the formula (II) can be made by the reaction of a ligand of the formula

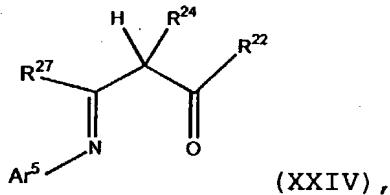

while compounds of the formula (VIII) can be made from the protonated form of (XIII). (XIII) can be made from the corresponding salicylaldehyde (when R<sup>10</sup> is hydrogen) and aromatic amine, followed by reaction with 5 an alkali metal base (such as an alkali metal hydride) to form the aryloxide.

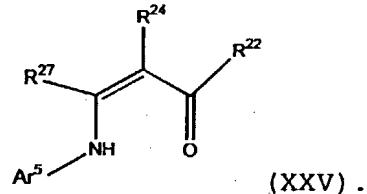

(III) and (IX) can be made by reacting pyrrole-2-carboxyaldehyde with the appropriate aromatic amine to form the pyrrole-2-imine, followed by reaction 10 with a strong base to form the pyrrole anion, and then reaction with the nickel precursors described above to form the nickel[II] complex.

Similarly, (IV) and (X) can be formed from an alkali metal thiophene-2-carboxylate and the nickel 15 precursors described above.

When K is CR<sup>27</sup> the ligand for (V) and (XI) can be made by the reaction of the corresponding ketone (which may contain other functional groups) with an aromatic amine to give

which is a tautomer of

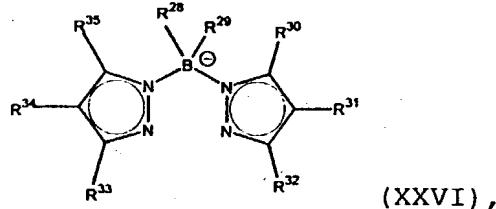

Useful ketones for making (V) and (XI) include ethyl acetoacetate, ethyl 2-ethylacetoacetate, isobutyl 25 acetoacetate, t-butyl acetoacetate, S-t-butyl acetoacetate, allyl acetoacetate, ethyl 2-methylacetoacetate, methyl 2-chloroacetoacetate, ethyl 2-chloroacetoacetate, methyl 4-chloroacetoacetate, ethyl 4,4,4-trifluoroacetoacetate, S-methyl 30 4,4,4-trifluoro-3-oxothiobutyrate, 2-methoxyethyl

When K is N in (V) and (XI), and R<sup>24</sup> is nitrile, the ligand can be made by the reaction of R<sup>22</sup>C(O)CH<sub>2</sub>CN with the diazonium salt of the corresponding arylamine, see for instance V.P. Kurbatov, et al., Russian Journal of 30 Inorganic Chemistry, vol. 42, p. 898-902 (1997). This paper also reviews methods of making ligands wherein K is CR<sup>27</sup>.

The boron containing ligands needed for compounds (VI) and (XII),

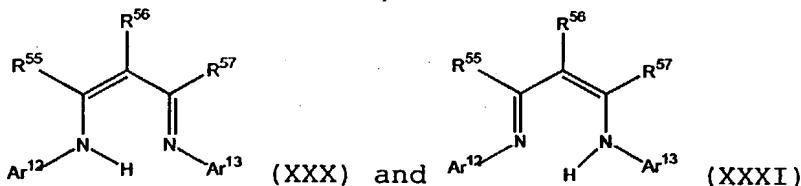

can be made by known procedures, see for instance S. Trofimenko, Prog. Inorg. Chem., vol. 34, p. 115-210 (1986) and S. Trofimenko, Chem. Rev., vol. 93, p. 943-980 (1993).

The synthesis of the tropolone-type ligands required for (XVIII) and (XIX) are described in J. J. Drysdale, et al., J. Am. Chem. Soc., vol. 80, p. 3672-3675 (1958); W. R. Brasen, et al., vol. 83, p. 3125-3138 (1961); and G. M. Villacorta, et al., J. Am. Chem. Soc., vol. 110, p. 3175-3182 (1988). These can be reacted as described above to form the corresponding nickel complex.

The ligand for (XXVII) and (XXVIII),

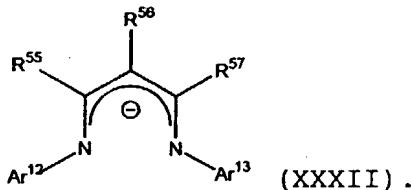

(XXIX),

or either of its tautomers,

can be made by reaction of the appropriate  $\alpha,\gamma$ -dioxo compound such as a 1,3-dione or 1,3-dial or similar compound with the appropriate aromatic amine, see for instance J. E. Parks, et al., Inorg. Chem., vol. 7, p. 1408 (1968); R. H. Holm, Prog. Inorg. Chem., vol. 14, p. 241 (1971); and P. C. Healy, et al., Aust. J. Chem., vol. 32, p. 727 (1979).

If the ligand precursor may form a tautomer, the ligand itself may usually be considered a tautomer. For instance, the monoanionic ligand derived from (XXIX) and its tautomers may be written as

In (XXVII) and (XXVIII) when L and/or G is N, the ligand can be made by the method described in Y.A. Ibrahim, et al., Tetrahedron, vol. 50, p. 5 11489-11498 (1994) and references described therein.

The ligands for (XXXVII) and (XXXXI) can be made by methods described in Phosphorous, Sulfur and Silicon, vol. 47, p. 401 et seq. (1990), and analogous reactions.

10 The ligands for (XXXVIII) and (XXXXII) can be made by reacting R<sub>2</sub>PLi (from R<sub>2</sub>PH and n-BuLi) with propylene sulfide to form R<sub>2</sub>CH<sub>2</sub>CH(CH<sub>3</sub>)SLi, and analogous reactions.

15 The ligands for (XXXIX) and (XXXXIII), and for (XXXX) and (XXXXIV) are commercially available. Those used herein were bought from Aldrich Chemical Co., Inc., Milwaukee, WI, U.S.A.

35  $R^{50}$ ,  $R^{51}$ ,  $R^{52}$ ,  $R^{53}$  and  $R^{54}$  are hydrogen; and/or

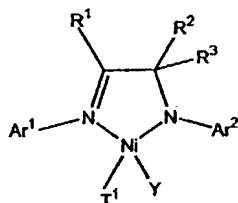

Ar<sup>10</sup> and Ar<sup>11</sup> are 2,6-dialkyl substituted phenyl, more preferably 2,6-dimethylphenyl or 2,6-diisopropylphenyl.

Monoanionic ligands which the olefins herein may 5 add to include hydride, alkyl, substituted alkyl, aryl, substituted aryl, or R<sup>26</sup>C(=O)- wherein R<sup>26</sup> is hydrocarbyl or substituted hydrocarbyl, and groups π-allyl and π-benzyl groups such as η<sup>3</sup>-C<sub>8</sub>H<sub>13</sub>, see for instance J. P. Collman, et al., Principles and 10 Applications of Organotransition Metal Chemistry, University Science Book, Mill Valley, CA, 1987. Such groups are also described in World Patent Application WO 96/23010.

In compound (XXXVI) it is preferred that R<sup>68</sup> is 15 -OR<sup>117</sup> or aryl, and/or R<sup>75</sup> is hydrocarbyl or substituted hydrocarbyl, and/or R<sup>76</sup> is hydrogen, hydrocarbyl, substituted hydrocarbyl or a functional group, more preferably hydrogen, hydrocarbyl or substituted hydrocarbyl.

20 In the second polymerization process described herein a nickel[II] complex such as any one of (VII)-(XII), (XIX), (XXVIII) or (XXXI)-(XXXIV) is either added to the polymerization process or formed in situ in the process. In fact, more than one such complex 25 may be formed during the course of the process, for instance formation of an initial complex and then reaction of that complex to form a living ended polymer containing such a complex.

An example of such a complex which may be formed 30 initially in situ is

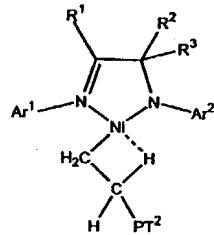

(XV)

wherein R<sup>1</sup> through R<sup>3</sup>, Ar<sup>1</sup> and Ar<sup>2</sup> are as defined above, T<sup>1</sup> is hydride, alkyl, or R<sup>42</sup>C(=O)- wherein R<sup>42</sup> 35 is hydrocarbyl or substituted hydrocarbyl or any other

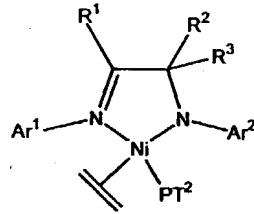

monoanionic ligand which ethylene may add to, and Y is a neutral ligand, or  $T^1$  and Y taken together are a bidentate monoanionic ligand which ethylene may add to. Similar complexes may also be formed with the ligands 5 in (VIII)-(XII), (XIX), (XXVIII) and (XXXI)-(XXXIV). Such complexes may be added directly to the process or formed in situ.

After the olefin polymerization has started, the complex may be in forms such as

10

(XVI) and

(XVII)

wherein  $R^1$  through  $R^3$ ,  $Ar^1$  and  $Ar^2$  are as defined 15 above, P is a divalent (poly)olefin group [the specific olefin shown in (XVI) and (XVII) is ethylene],  $-(CH_2)_x-$  wherein x is an integer of 2 or more, and  $T^2$  is an end group, for example the groups listed for  $T^1$  above. (XVI) is a so-called agostic form complex. Similar 20 complexes may also be formed with the ligands in (VIII)-(XII), (XI), (XXVIII) and (XXXI)-(XXXIV). Analogous compounds with other olefins in place of ethylene also may be formed. In all the polymerization processes herein, the temperature at which the olefin 25 polymerization is carried out is about  $-100^{\circ}C$  to about  $+200^{\circ}C$ , preferably about  $0^{\circ}C$  to about  $150^{\circ}C$ , more preferably about  $25^{\circ}C$  to about  $100^{\circ}C$ . The olefin concentration at which the polymerization is carried out is not critical, atmospheric pressure to about 275 30 MPa being a suitable range for ethylene and propylene.

The polymerization processes herein may be run in the presence of various liquids, particularly aprotic organic liquids. The catalyst system, olefin, and polyolefin may be soluble or insoluble in these 5 liquids, but obviously these liquids should not prevent the polymerization from occurring. Suitable liquids include alkanes, cycloalkanes, selected halogenated hydrocarbons, and aromatic hydrocarbons. Hydrocarbons are the preferred solvent. Specific useful solvents 10 include hexane, toluene, benzene, chloroform, methylene chloride, 1,2,4-trichlorobenzene, p-xylene, and cyclohexane.

The catalysts herein may be "heterogenized" by coating or otherwise attaching them to solid supports, 15 such as silica or alumina. Where an active catalyst species is formed by reaction with a compound such as an alkylaluminum compound, a support on which the alkylaluminum compound is first coated or otherwise attached is contacted with the nickel compound 20 precursor to form a catalyst system in which the active nickel catalyst is "attached" to the solid support. These supported catalysts may be used in polymerizations in organic liquids, as described in the immediately preceding paragraph. They may also be used 25 in so-called gas phase polymerizations in which the olefin(s) being polymerized are added to the polymerization as gases and no liquid supporting phase is present.

Included herein within the definitions of all the 30 polymerization processes are mixtures of starting materials that lead to the formation *in situ* of the nickel compounds specified in all of the polymerization processes.

In the Examples all pressures are gauge pressures. 35 Quantitative  $^{13}\text{C}$  NMR data for the polymers was obtained using a 10 mm probe on typically 15-20% solutions of the polymer and 0.05M  $\text{Cr}(\text{acetylacetonate})_3$  in 1,2,4-trichlorobenzene are 120-140°C. For a full

description of determination of branching by  $^{13}\text{C}$  and  $^1\text{H}$  NMR, and for a definition of branches, see World Patent Application 96/23010, which is hereby included by reference.

Ligand Syntheses

Ligand syntheses and deprotonations were carried out according to the general procedures given below unless stated otherwise. The general procedure for imine synthesis is based upon published procedures for the synthesis of N-aryl-substituted imines given in the following reference: Tom Dieck, H.; Svoboda, M.; Grieser, T. *Z. Naturforsch* **1981**, *36b*, 823 - 832. The synthesis of  $\text{ArN}=\text{CH}-\text{CH}(t\text{-Bu})-\text{N}(\text{Ar})(\text{Li})$  [ $\text{Ar} = 2,6\text{-(i-Pr)}_2\text{C}_6\text{H}_3$ ] is based on the published synthesis of  $(t\text{-Bu})\text{N}=\text{CH}-\text{CH}(t\text{-Bu})-\text{N}(t\text{-Bu})(\text{Li})$ : Gardiner, M. G.; Raston, C. L. *Inorg. Chem.* **1995**, *34*, 4206 - 4212. The synthesis of  $\text{ArN}=\text{C}(\text{Me})-\text{CH}=\text{C}(\text{Me})-\text{NH}(\text{Ar})$  [ $\text{Ar} = 2,6\text{-(i-Pr)}_2\text{C}_6\text{H}_3$ ] was published in WO Pat. Appl. 96/23010, and it was deprotonated according to the general procedure given below. The bis(pyrazolyl)borate anions that were used to synthesize complexes 18 and 19 were provided by S. Trofimenko (DuPont) and were synthesized according to the procedures published in the following review: Trofimenko, S. *Chem. Rev.* **1993**, *93*, 943.

General Procedure for Imine Synthesis. In a fume hood, formic acid catalyst was added to a methanol solution of the aldehyde and the aniline (~1.1 - 1.2 equiv). The reaction mixture was stirred and the resulting precipitate was collected on a frit and washed with methanol. The product was then dissolved in  $\text{Et}_2\text{O}$  or  $\text{CH}_2\text{Cl}_2$  and stirred over  $\text{Na}_2\text{SO}_4$  overnight. The solution was filtered through a frit with Celite® and the solvent was removed in vacuo to yield the product.

General Procedure for the Synthesis of Sodium Salts. The protonated forms of the ligands were dissolved in anhydrous THF in the drybox. Solid  $\text{NaH}$  was slowly added to the solution, and then the reaction mixture was stirred overnight. The next day, the solution was filtered through a frit with dry Celite®. The solvent was removed and the resulting powder was

dried in vacuo. With some exceptions (e.g., Example 1), the sodium salts were not soluble in pentane and were further purified by a pentane wash.

Example 1

A drop of formic acid was added to a solution of 1,2-cyclohexanedione (0.25 g, 2.2 mmol) and 2,6-diisopropylaniline (0.85 mL, 4.5 mmol) in 5 mL of methanol. The reaction mixture was stirred at rt for 3 days. The white solid thus formed was filtered, washed with a small amount of methanol and dried under vacuum. After recrystallization from hot methanol, the product (0.4 g; 41% yield; mp 81-83 °C) was isolated as white crystals:  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 300 MHz, rt):  $\delta$  7.28 - 7.08 (m, 6, Haryl), 6.45 (s, 1, NH), 4.84 (t, 1,  $J = 4.6$ ,  $\text{CH}=\text{CNHAr}$ ), 3.30 (septet, 2,  $J = 6.88$ ,  $\text{CHMe}_2$ ), 2.86 (septet, 2,  $J = 6.87$ ,  $\text{C}'\text{HMe}_2$ ), 2.22 (m, 4,  $\text{ArN}=\text{CCH}_2\text{CH}_2-$ ), 1.75 (m, 2,  $\text{CH}_2\text{CH}=\text{CNHAr}$ ), 1.24 and 1.22 (d, 12 each,  $\text{CHMe}_2$  and  $\text{C}'\text{HMe}_2$ );  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 300 MHz, rt)  $\delta$  162.1, 147.3, 145.8, 139.6, 137.0, and 136.4 ( $\text{ArNH}-\text{C}-\text{C}=\text{NAr}$ , Ar: Cipso,  $\text{C}_6$ ; Ar': Cipso,  $\text{C}_6$ ), 126.5, 123.4, 123.3 and 122.9 (Ar:  $\text{C}_p$ ,  $\text{C}_m$ ; Ar':  $\text{C}_p$ ,  $\text{C}_m$ ), 106.0 ( $\text{ArNHC}=\text{CH}-$ ), 29.3, 28.4 and 28.3 ( $\text{ArNHC}=\text{CH}-\text{CH}_2\text{CH}_2\text{CH}_2\text{C}=\text{NAr}$ ), 24.2 and 23.30 ( $\text{CHMe}_2$ ,  $\text{C}'\text{HMe}_2$ ), 23.25 and 22.9 ( $\text{CHMe}_2$ ,  $\text{C}'\text{HMe}_2$ ).

The sodium salt was cleanly synthesized according to the above general procedure:  $^1\text{H}$  NMR (300 MHz,  $\text{THF}-d_8$ ): no THF coordinated.

In a nitrogen-filled drybox,  $t\text{-BuLi}$  (7.81 mL of a 1.7 M solution in pentane) was filtered through a short plug of dry Celite® into a round bottom flask. The flask was cooled to -35°C in the drybox freezer. Synthesis of Nickel Complexes

General Synthesis of Nickel Allyl Initiators. A mixture of two equiv of the appropriate anionic ligand and one equiv of  $[(\text{allyl})\text{Ni}(\mu-\text{X})]_2$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ) was dissolved in THF. The reaction mixture was stirred for several h before being filtered. The solvent was removed in vacuo to yield the desired product. Depending on the solubility of the product, further purification was often carried out by dissolving the 20 product in  $\text{Et}_2\text{O}$  or pentane and filtering again or washing the product with  $\text{Et}_2\text{O}$  or pentane. Due to ease of characterization and, especially, ease of initiation in the presence of a Lewis acid, typically allyl = (a)  $\text{H}_2\text{CC}(\text{CO}_2\text{Me})\text{CH}_2$ . However, other allyl derivatives were 25 also synthesized and their polymerization activity explored; these include allyl = (b)  $\text{H}_2\text{CCHCH}_2$ , (c)  $\text{H}_2\text{CCHCHMe}$ , (d)  $\text{H}_2\text{CCHCMe}_2$ , (f)  $\text{H}_2\text{CCHCHCl}$ , and (g)  $\text{H}_2\text{CCHCHPh}$ . The  $[(\text{allyl})\text{Ni}(\mu-\text{X})]_2$  precursors were 30 synthesized according to the procedures published in the following reference: Wilke, G.; Bogdanovic, B.; Hardt, P.; Heimbach, P.; Keim, W.; Kroner, M.; Oberkirch, W.; Tanaka, K.; Steinrucke, E.; Walter, D.;

Ethylene and Propylene Polymerization Procedures and Reactions

The results of ethylene and propylene polymerizations catalyzed by complexes 1-20 under various reaction conditions (see general procedures and Table 1 below) are reported in Tables 2-5. The polymers were characterized by NMR, GPC, and DSC analysis. A description of the methods used to analyze the amount and type of branching in polyethylene samples by  $^{13}C$  NMR spectroscopy is given in WO Pat. Appl. 96/23010. GPC's were run in trichlorobenzene at  $135^{\circ}C$  and calibrated against polystyrene standards.

General Procedure for the Screening of Ethylene

30 Polymerizations by Nickel Allyl Initiators at 6.9 MPa Ethylene.

In the drybox, a glass insert was loaded with the isolated allyl initiator. The insert was cooled to  $-35^{\circ}C$  in the drybox freezer, 5 mL of solvent (typically  $C_6D_6$  or  $CDCl_3$ ) was added to the cold insert, and the insert was cooled again. A Lewis acid cocatalyst [typically  $BPh_3$  or  $B(C_6F_5)_3$ ] was often added to the cold solution, and the insert was then capped and

sealed. Outside of the drybox, the cold tube was placed under ethylene (typically 6.9 MPa) and allowed to warm to rt as it was shaken mechanically for approximately 18 h. An aliquot of the solution was 5 used to acquire a  $^1\text{H}$  NMR spectrum. The remaining portion was added to ~20 mL of MeOH in order to precipitate the polymer. The polyethylene was isolated and dried under vacuum.

General Procedure for the Screening of Ethylene

10 Polymerizations by Nickel Allyl Initiators at 28-35 kPa Ethylene with Polymethylaluminoxane (PMAO) Cocatalyst.

In the drybox, the nickel complex was placed in a Schlenk flask and dissolved in ~ 20 mL of toluene. The flask was sealed, removed from the drybox and attached 15 to an ethylene line where it was purged with first nitrogen and then ethylene. After purging with ethylene, PMAO was quickly added to the reaction mixture and the flask was placed under 28-35 kPa of ethylene. After being stirred overnight, the reaction 20 mixture was quenched with ~15 mL of a solution of concentrated HCl in methanol (10:90 volume percent solution). The polymer was collected on a frit, washed with methanol and then acetone and then dried in vacuo overnight.

25 General Procedure for the Screening of Propylene Polymerization by Nickel Allyl Initiators at 48 kPa Propylene with Polymethylaluminoxane (PMAO) Cocatalyst.

In the drybox, the nickel complex was placed in a Schlenk flask and dissolved in ~ 10 mL of toluene. The 30 flask was sealed, removed from the drybox and attached to an ethylene line where it was purged with first nitrogen and then propylene. After purging with propylene, PMAO was quickly added to the reaction mixture and the flask was placed under ~ 48 kPa of propylene. After being stirred overnight, the reaction 35 mixture was quenched with ~ 10 mL of a solution of concentrated HCl in methanol (10:90 volume percent solution). The polymer was collected on a frit, washed

with methanol and then acetone and then dried in vacuo overnight.

Polymerization by Nickel Allyl Initiators at 48 kPa

5 Propylene with B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> Cocatalyst.

In the drybox, the nickel complex was placed in a Schlenk flask and dissolved in ~10 mL of CH<sub>2</sub>Cl<sub>2</sub>. Two equiv of B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> were dissolved in a minimal amount of CH<sub>2</sub>Cl<sub>2</sub> and the solution was transferred to the Schlenk 10 flask. The flask was sealed, removed from the drybox and attached to an ethylene line where it was purged with first nitrogen and then propylene. The flask was placed under ~48 kPa of propylene and the reaction mixture was stirred overnight and then was quenched 15 with ~10 mL of a solution of concentrated HCl in methanol (10:90 volume percent solution). The polymer was collected on a frit, washed with methanol and then acetone and then dried in vacuo overnight

20 General Procedure for the Screening of Propylene  
Polymerization by Nickel Allyl Initiators at 600 kPa

Propylene with B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> Cocatalyst.

In the drybox, the nickel complex was placed in a vessel and dissolved in ~20 mL of CH<sub>2</sub>Cl<sub>2</sub>. Two equiv of B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> were dissolved in 10 mL of CH<sub>2</sub>Cl<sub>2</sub> and placed 25 in a separate vessel. Both vessels were sealed and removed from the drybox. The solution of the nickel complex was transferred to a 100 mL Parr reactor under vacuum and the solution of B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> was transferred to the addition port of the same reactor. The B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> 30 solution was forced into the reactor ~600 kPa of propylene. The reactor pressure was maintained at 600 kPa and the reaction mixture was stirred for 3 h. Next, the reaction mixture was quenched with ~ 10 mL of a solution of concentrated HCl in methanol (10:90 35 volume percent solution). If polymer was present, it was collected on a frit, washed with methanol and then acetone and then dried in vacuo overnight. Oligomers were characterized by GC analysis.

Examples 131-136Styrene and Norbornene Homo- and Copolymerizations

In the subsequent examples describing polymerizations of styrene and norbornene, all manipulations were carried out in a nitrogen-purged drybox. Anhydrous solvents were used. The styrene (99+%, Aldrich, inhibited with 4-tert-butylcatechol) was degassed, filtered through basic alumina and inhibited with phenothiazine (98+%, Aldrich, 50 ppm) before use. The norbornene was purified by vacuum sublimation. Tacticities of polystyrenes were measured according to the following reference: T Kawamura et al., *Macromol. Rapid Commun.* **1994**, *15*, 479-486.

General Procedure for Styrene Polymerizations.

The nickel complex (0.03 mmol) was slurried in dry toluene (6 mL) and styrene (1.3 mL, 1.18 g, 11.3 mmol) was added. Two equiv of  $B(C_6F_5)_3$  were then added with vigorous stirring. The resulting mixture was shaken at rt in the dark for 16 h after which time the sample was removed from the drybox and MeOH was added to precipitate the polymer. The solid polymer was isolated, redissolved in  $CHCl_3$  and reprecipitated with MeOH to remove catalyst impurities. The product was then collected on a frit, washed with MeOH and finally with a MeOH/acetone/Irganox® 1010 solution.

General Procedure for Norbornene Polymerizations.

The nickel complex (0.03 mmol) was slurried in dry toluene (6 mL) and norbornene (1.6 g, 17.0 mmol) was added. Two equiv of  $B(C_6F_5)_3$  were then added with vigorous stirring. The resulting mixture was shaken at rt. After 16 h, the sample was removed from the drybox and MeOH was added to precipitate the polymer. The solid polymer was isolated. The polymer was redissolved or swollen with solvent in order to remove catalyst impurities and then reprecipitated with MeOH. The product was then collected on a frit, washed with MeOH and finally with an acetone/2% Irganox® 1010 solution.

General Procedure for Styrene/Norbornene

Copolymerizations. The nickel complex (0.03 mmol) was slurried in dry toluene (5 mL) and a mixture of norbornene (1.17 g, 12.4 mmol) and styrene (1.4 mL, 5 1.27 g, 12.2 mmol) in toluene (3 mL) was added. Two equiv of  $B(C_6F_5)_3$  were then added with vigorous stirring. The resulting mixture was shaken at rt in the dark for 5 h. The sample was then removed from the drybox and MeOH was added to precipitate the polymer.

10 The isolated polymer was dissolved ( $CHCl_3$ ) and reprecipitated (MeOH) to remove the catalyst residue. The product was stirred overnight in acetone to remove polystyrene and then filtered, washed with MeOH and finally with an acetone/2% Irganox® 1010 solution.

Norbornene Homopolymerizations and

Norbornene/Functionalized-Norbornene Copolymerizations

Example 188Norbornene Homopolymerization Catalyzed by 52/B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub>.

In a 20 mL scintillation vial under nitrogen, compound **52** (0.010 g, 0.021 mmol) and norbornene (1.00 g, 10.62 mmol) were dissolved in 5 mL of toluene to give an orange solution. To this was added B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> (0.011 g, 0.022 mmol). After 30 min at ambient temperature, more B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> was added to the reaction mixture (0.110 g, 0.214 mmol). An extremely viscous, yellow suspension formed very rapidly and within minutes the reaction mixture could no longer be stirred. Twenty-three h after the initial addition of B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub>, the reaction mixture was quenched by addition of methanol under air. Further workup afforded 0.93 g of polymer. <sup>1</sup>H NMR (1,1,2,2-tetrachloroethane-*d*<sub>2</sub>, 120°C) indicated that the polymer was the addition polymer of norbornene formed without double bond ring-opening.

Example 189

20 Copolymerization of Norbornene with the Dimethyl Ester of endo-5-Norbornene-2,3-Dicarboxylic Acid Catalyzed by 21a/B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> (Copolymer: ~30 Mole % Dimethyl Ester)

In a 20 mL scintillation vial under nitrogen, compound **21a** (0.015 g, 0.029 mmol), norbornene (0.500 g, 5.31 mmol), and the dimethyl ester of 5-norbornene-2,3-dicarboxylic acid (1.00 g, 4.76 mmol) were dissolved in 10 mL of toluene. To this solution was added solid B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> (0.029 g, 0.058 mmol). The resulting solution was stirred initially at ambient temperature by means of a magnetic stirbar; however, after several minutes the reaction mixture consisted of a viscous, solvent-swollen polymer that could not be stirred. Twenty-seven h after the addition of B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub>, the reaction mixture was quenched by addition of the solvent-swollen reaction mixture to methanol under air. The precipitated polymer was filtered off, washed with methanol, and dried to afford 0.810 g of addition copolymer. <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>, 25 °C) indicated the

following composition: norbornene (74 mole %), dimethyl ester (26 mole %). Quantitative  $^{13}\text{C}$  NMR (trichlorobenzene- $d_3$ , 100 °C) indicated the following composition: norbornene (70.8 mole %), dimethyl ester (29.2 mole %).

Example 190

Copolymerization of Norbornene with the Dimethyl Ester of endo-5-Norbornene-2,3-Dicarboxylic Acid Catalyzed by 21a/B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> (Copolymer: ~22 Mole % Dimethyl Ester)

10 A reaction identical to that above in Example 189, but run in CH<sub>2</sub>Cl<sub>2</sub> instead of toluene gave the following results: Yield = 0.63 g.  $^1\text{H}$  NMR (CDCl<sub>3</sub>, 25 °C) indicated the following composition: norbornene (81%), dimethyl ester (19%). Quantitative  $^{13}\text{C}$  NMR (trichlorobenzene- $d_3$ , 100 °C): norbornene (78.11 mole %), dimethyl ester (21.89 mole %).

Example 191

Copolymerization of Norbornene with the Dimethyl Ester of endo-5-Norbornene-2,3-Dicarboxylic Acid Catalyzed by 21a/B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> (Copolymer: ~11 mole % Dimethyl Ester)

20 In a 20 mL scintillation vial under nitrogen, compound 21a (0.015 g, 0.029 mmol), norbornene (3.00 g, 31.86 mmol), the dimethyl ester of 5-norbornene-2,3-dicarboxylic acid (1.00 g, 4.76 mmol), and B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> (0.029 g, 0.058 mmol) were dissolved in 10 mL of toluene. The resulting yellow solution was stirred initially at ambient temperature by means of a magnetic stirbar; however, within 15 minutes an extremely rapid, highly exothermic reaction ensued. The reaction mixture setup and could not be stirred after this point. Three h after the addition of B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub>, the reaction mixture was quenched by addition of the solvent-swollen reaction mixture to methanol under air. Further workup afforded 3.75 g of addition copolymer.

25  $^1\text{H}$  NMR (CDCl<sub>3</sub>, 25 °C) indicated the following composition: norbornene (90 mole %), dimethyl ester (10 mole %). Quantitative  $^{13}\text{C}$  NMR (trichlorobenzene- $d_3$ ,

100 °C) indicated the following composition: norbornene (89.05 mole%), dimethyl ester (10.95 mole%).

Example 192

A reaction identical to that above in Example 191, but run in CH<sub>2</sub>Cl<sub>2</sub> instead of toluene gave the following results: Yield = 3.12 g. <sup>1</sup>H NMR (CDCl<sub>3</sub>, 25 °C)

10 indicated the following composition: norbornene (96 mole %), dimethyl ester (4 mole %). Quantitative <sup>13</sup>C NMR (trichlorobenzene-d<sub>3</sub>, 100 °C): norbornene (94.19 mole %), dimethyl ester (5.81 mole %).

Example 193

15 Copolymerization of Norbornene with the t-Bu Ester of 5-Norbornene-2-Carboxylic Acid Catalyzed by 50/B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> (Copolymer: ~30 mole % t-Bu Ester)

In a 20 mL scintillation vial under nitrogen, compound 50 (0.010 g, 0.020 mmol), norbornene (0.500 g, 20 5.31 mmol), and the t-Bu ester of 5-norbornene-2-carboxylic acid (1.00 g, 5.15 mmol) were dissolved in 5 mL toluene. To this solution was added B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> (0.102 g, 0.200 mmol). The resulting yellow solution was stirred at ambient temperature for 16 h. The reaction 25 mixture was quenched and the copolymer precipitated by addition of methanol under air. Further workup afforded 0.664 g of addition copolymer. Ethylene Polymerizations

General Procedure for Ethylene Polymerizations  
of Table 9

20 Pressure Tube Loaded Outside of the Drybox Under a  
Nitrogen Purge

(In the ethylene polymerization reactions of Tables 2, 3, and 4, the glass inserts were also loaded in the pressure reactor tube outside of the drybox under a nitrogen purge.) Procedure. In the drybox, a glass insert was loaded with the isolated allyl initiator (0.06 mmol). The insert was cooled to -35 °C in the drybox freezer, 5 mL of  $C_6D_6$  was added to the cold insert, and the insert was cooled again. A Lewis acid cocatalyst [typically  $BPh_3$  or  $B(C_6F_5)_3$ ] was added to the cold solution, and the insert was then capped and sealed. Outside of the drybox, the cold insert was placed under a nitrogen purge into the pressure tube. The pressure tube was sealed, placed under ethylene (6.9 MPa), and allowed to warm to rt as it was shaken mechanically for approximately 18 h. An aliquot of the solution was used to acquire a  $^1H$  NMR spectrum. The remaining portion was added to ~20 mL of MeOH in order

to precipitate the polymer. The polyethylene was isolated and dried under vacuum.

General Procedure for Ethylene Polymerizations of Tables 10-14:

5 Pressure Tube Loaded and Sealed in the Drybox under a Nitrogen Atmosphere

Procedure. In the drybox, a glass insert was loaded with the nickel compound. Often, a Lewis acid (typically  $BPh_3$  or  $B(C_6F_5)_3$ ) was also added to the glass 10 insert. Next, 5 mL of a solvent (typically 1,2,4-trichlorobenzene although *p*-xylene, cyclohexane, etc. were also used at times) was added to the glass insert and the insert was capped. The glass insert was then loaded in the pressure tube inside the drybox. The 15 pressure tube containing the glass insert was then sealed inside of the drybox, brought outside of the drybox, connected to the pressure reactor, placed under the desired ethylene pressure and shaken mechanically. After the stated reaction time, the ethylene pressure 20 was released and the glass insert was removed from the pressure tube. The polymer was precipitated by the addition of MeOH (~20 mL) and concentrated HCl (~1-3 mL). The polymer was then collected on a frit and rinsed with HCl, MeOH, and acetone. The polymer was 25 transferred to a pre-weighed vial and dried under vacuum overnight. The polymer yield and characterization were then obtained.

Oligomerizations. In the drybox under a nitrogen 5 atmosphere, the nickel compound (0.03 mmol) was placed in a vial. Next, 5 mL of toluene was added to the vial followed by 1.3 mL of cyclopentene.  $B(C_6F_5)_3$  (40 mg) was then added to the vial. The reaction mixture was mixed for 3 d on a vortexer and then removed from the 10 drybox and added to 100 mL of stirring methanol. No polymer precipitated. GC analysis was carried out on the organic layer. The results are reported in Table 15 below.

Polymerizations. In a nitrogen-filled drybox, the 5 nickel compound (0.06 mmol) and the Lewis acid (5 equiv) were placed together in a glass insert. The insert was cooled to -30 °C in the drybox freezer. 5 mL of cold ethyl 4-pentenoate was added to the cold insert, and the insert was recooled in the drybox 10 freezer. The cold inserts were removed from the drybox and placed under a nitrogen purge in a pressure tube, which was then sealed and pressurized to 6.9 MPa of ethylene and mechanically shaken for 18 h. The pressure was then released and the glass insert was 15 removed from the pressure tube and the polymer was precipitated in MeOH, collected on a frit, and dried in vacuo. Characteristic NMR resonances of the copolymer include the 4.01 OCH<sub>2</sub> resonance in the <sup>1</sup>H NMR and the 59.7 OCH<sub>2</sub> resonance and ~172.4 C=O resonances in the <sup>13</sup>C 20 NMR spectrum.

General Procedure for Ethylene Polymerizations of Table

17:

Ethylene Polymerizations in the Parr® Reactor

Procedure. Prior to conducting the polymerization, the Parr® reactor flushed with nitrogen, heated under vacuum overnight, and then allowed to cool to room temperature. In the drybox, a glass vial was loaded with the nickel compound, Lewis acid and solvent and then capped with a rubber septum.

The solution of the nickel complex and Lewis acid was then transferred to a 100 mL Parr reactor under vacuum, and the reactor was pressurized with ethylene and the reaction mixture was mechanically stirred. After the 5 stated reaction time, the ethylene pressure was released, and the polymer was precipitated by adding the reaction mixture to a solution of MeOH (~100 mL) and concentrated HCl (~1-3 mL). The polymer was then collected on a frit and rinsed with HCl, MeOH, and 10 acetone. The polymer was transferred to a pre-weighed vial and dried under vacuum overnight. The polymer yield and characterization were then obtained.

Example 438

Ethylene Polymerization Using (acac)Ni(Et)PPh<sub>3</sub>

10 Precursor at 6.9 MPa

In the drybox, a glass insert was loaded with (acac)Ni(Et)PPh<sub>3</sub> (26.9 mg, 0.06 mmol) and [2-(NaO)-3,5-(*t*-Bu)<sub>2</sub>-C<sub>6</sub>H<sub>2</sub>-C(Me)=NAr (Ar = 2,6-(*i*-Pr)<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>) · 0.5 THF] (25.8 mg, 1 equiv). The insert was cooled to -35 °C in 15 the drybox freezer, 5 mL of C<sub>6</sub>D<sub>6</sub> was added to the cold insert, and the insert was cooled again. BPh<sub>3</sub> (29.1 mg, 2 equiv) was added to the cold solution, and the insert was then capped and sealed and cooled again. Outside of the drybox, the cold insert was placed under 20 a nitrogen purge into the pressure tube. The pressure tube was sealed, placed under ethylene (6.9 MPa), and allowed to warm to rt as it was shaken mechanically for approximately 18 h. Polyethylene (16.5 g, 9,820 TO)

was isolated as a powder following precipitation from methanol.

Example 439

Ethylene Polymerization Using NiBr<sub>2</sub> Precursor at 28-35

5

MPa

The sodium salt of the ligand of Example 1 (1.01 g, 2.23 mmol), e.g.

was placed in a round bottom flask in the drybox 10 together with 487 mg (2.23 mmol) of NiBr<sub>2</sub>. THF (20 mL) was added and the solution was stirred for ~2 months. The THF was removed in vacuo and the product was dissolved in CH<sub>2</sub>Cl<sub>2</sub> and the resulting solution was filtered. The solvent was removed and the product was 15 dried in vacuo. An orange powder (488 mg) was isolated. (In addition to CD<sub>2</sub>Cl<sub>2</sub>, the product was also soluble in C<sub>6</sub>D<sub>6</sub>. <sup>1</sup>H NMR spectra in both solvents were complex.)

In the drybox, a glass Schlenk flask was loaded 20 with the resulting orange nickel compound (17 mg, ~0.03 mmol), 35 mL of toluene and a stir bar. The flask was then capped with a rubber septum and the stopcock was closed prior to removing the flask from the drybox. The flask was then attached to the ethylene line where 25 it was evacuated and backfilled with ethylene. MAO-IP (2 mL, ~94 equiv) was added to the flask via cannula. The reaction mixture was stirred under ethylene for 3.5 h, the ethylene pressure was then released, and the polymer was precipitated by adding the reaction mixture 30 to a solution of MeOH (~100 mL) and concentrated HCl (~1-3 mL). The polymer was then collected on a frit and rinsed with MeOH. The polymer was transferred to a pre-weighed vial and dried under vacuum overnight. A white polyethylene film (5.09 g, ~6050 TO) was 35 isolated.

[For the preparation of (*tmeda*) $\text{NiMe}_2$  please see: Kaschube, W.; Porschke, K. R.; Wilke, G. J. *Organomet. Chem.* **1988**, 355, 525 - 532.] The reaction mixture was stirred for ~ 4 h. The solution was then filtered though a frit with dry Celite®. The 30 solvent was removed and the product was dried in vacuo.

General Procedure for Ethylene(28-35 kPa)/ $\alpha$ -Olefin

Copolymerizations of Table 19

10 In the drybox, a glass Schlenk flask was loaded with the nickel compound, Lewis acid, solvent, comonomer, and a stir bar. The flask was then capped with a rubber septum and the stopcock was closed prior to removing the flask from the drybox. The flask was 15 then attached to the ethylene line where it was evacuated and backfilled with ethylene. The reaction mixture was stirred under ethylene for the stated reaction time, the ethylene pressure was then released, and the polymer was precipitated by adding the reaction 20 mixture to a solution of MeOH (~100 mL) and concentrated HCl (~1-3 mL). The solid polymer was then collected on a frit and rinsed with MeOH. For amorphous polymers, the MeOH was decanted off of the polymer. Often, the amorphous polymer was dissolved in 25 hexane and reprecipitated in methanol. The polymer was transferred to a pre-weighed vial and dried under vacuum overnight. The polymer yield and characterization were then obtained.

For Example 505 the following quantitative  $^{13}\text{C}$  NMR (TCB, 120-140°C) was obtained: Branching per 1000  $\text{CH}_2$ 's; total methyls (98.4), methyl (54.5), ethyl (13.1), propyl (3.2), butyl (14.4), amyl (4.9), hexyl and greater and end of chains (11.1), amyl and greater and end of chains (13.7), butyl and greater and end of chains (27.6)

In the drybox, the nickel compound, Lewis acid, solvent, monomer and stir bar were placed together in a round bottom flask. The reaction mixture was stirred for the stated amount of time. The flask was removed from the drybox and water and concentrated hydrochloric acid were added. The product was extracted with toluene and/or hexane and the solution was filtered through a frit containing a layer of neutral alumina on

top of a layer of silica gel. The solvent was then evaporated and the product was dried in vacuo.
